                                                                       FILTER CALL
The directory of the file
                                                                       Call a user-defined function to filter data
                                                                       Directory constants
Name of the function
                                                                       Directory name
Class name, includes the namespace it was declared in
                                                                        FILE
                                                                       Filename along with directory
The trait name, also includes the namespace
                                                                       Line number
                                                                       Variable-handling functions
The class method name
                                                                        boolval()
Name of the current namespace
                                                                       Used to retrieve the boolean value of a variable
Error constants
                                                                       debug zval dump()
E ERROR
                                                                       Outputs a string representation of an internal zend value
Fatal run-time errors that cause the halting of the script and
can't be recovered from
                                                                       Checks whether a variable is empty or not
Non-fatal run-time errors, execution of the script continues
                                                                       Get the float value of a variable (doubleval is another possibility)
                                                                       get_defined_vars()
                                                                       Returns an array of all defined variables
Compile-time parse errors, should only be generated by the
parser
                                                                       get resource type(
                                                                       Returns the resource type
Run-time notices that indicate a possible error
                                                                       gettype()
                                                                       Retrieves the variable type
Fatal errors at PHP initialization, like an E_ERROR in PHP core
                                                                        import request variab
                                                                       Import GET/POST/Cookie variables into the global scope
Non-fatal errors at PHP startup, similar to E_WARNING but in PHP
                                                                       Find the integer value of a variable
core
                                                                       is array(
Fatal compile-time errors generated by the Zend Scripting Engine
                                                                       Checks whether a variable is an array
                                                                       is bool(
Non-fatal compile-time errors by the Zend Scripting Engine
                                                                       Finds out if a variable is a boolean of 538
                                                                       is callable(
Fatal user-generated error, set by the programmer using
                                                                       Verify whether you can call the contents of a variable as a function
trigger_error()
                                                                       Check whether the contents of a variable are countable
Non-fatal user-generated warning
                                                                       is_float()
                                                                       Find out if the type of a variable is float, alternatives: is_double
 USER NOTICE
User-generated notice by trigger_error()
                                                                       and is real
                                                                       is int(
                                                                       Check if the type of a variable is an integer, is_integer and
Suggestions by PHP to improve your code (needs to be enabled)
                                                                       is_long also works
Catchable fatal error caught by a user-defined handle
                                                                       Verify that a variable's content is an iterable value
Enable this to receive warnings about a code which is not
future-proof
                                                                       Checks whether a variable's value is NULL
 _USER_DEPRECATED
User-generated warning for deprecated code
                                                                       Find out if a variable is a number or a numeric string
                                                                       is object()
All errors and warnings except E_STRICT
                                                                       Determines whether a variable is an object
Filter constants
                                                                       is resource()
                                                                       Check if a variable is a resource
FILTER VALIDATE BOOLEAN
                                                                       is_scalar()
Validates a Boolean
FILTER_VALIDATE_EMA
                                                                       Tests if a variable is a scalar
Certifies an e-mail address
                                                                       is string(
                                                                       Find out whether the type of a variable is a string
Confirms a float
                                                                       isset()
FILTER_VALIDATE_IN
                                                                       Determine if a variable has been set and is not NULL
Verifies an integer
                                                                       print r(
                                                                       Provides human-readable information about a variable
FILTER VALIDATE II
Validates an IP address
                                                                        serialize(
FILTER_VALIDATE_REGEXP
                                                                       Generates a representation of a value that is storable
Confirms a regular expression
                                                                        settype()
FILTER_VALI
                                                                       Sets a variable's type
Validates a URL
                                                                       Retrieves the string value of a variable
```

Removes all illegal characters from an e-mail address

```
unserialize()
                                                                       array search(
Creates a PHP value from a stored representation
                                                                       Searches the array for a given value and returns the first key if
                                                                       successful
unset()
Unsets a variable
                                                                        arrav shift()
var_dump()
                                                                       Shifts an element from the beginning of an array
Dumps information about a variable
                                                                        array_slice()
                                                                       Extracts a slice of an array
var export()
Outputs or returns a string representation of a variable that
                                                                        array_splice()
can be parsed
                                                                       Removes a portion of the array and replaces it
Array functions
                                                                       array sum()
array change key_case()
                                                                       Calculate the sum of the values in an array
Changes all keys in an array to uppercase or lowercase
                                                                       array udiff()
array chunk()
                                                                       Compare arrays and return the difference using a user function
Splits an array into chunks
                                                                        (values only)
array_column()
                                                                        array_udiff_assoc()
Retrieves the values from a single column in an array
                                                                       Compare arrays and return the difference using a default and a user
array_combine()
                                                                        function (keys and values)
Merges the keys from one array and the values from another
                                                                        array_udiff_uassoc()
into a new arrav
                                                                       Compare arrays and return the difference using two user functions
array_count_values()
                                                                        (values and keys)
Counts all values in an array
                                                                        array_uintersect()
                                                                       Compare arrays and return the matches via user function
array diff(
Compares arrays, returns the difference (values only
                                                                        (values only)
array_diff_assoc()
                                                                        array_uintersect_assoc()
Compares arrays, returns the difference (values and keys)
                                                                       Compare arrays and return the matches via a default user function
array_diff_key()
                                                                       (keys and values)
Compares arrays, returns the difference (keys only)
                                                                        array_uintersect_uassoc()
array_diff_uassoc(
                                                                        Compare arrays and return the matches via two user functions
Compares arrays (keys and values) through a user callback
                                                                       (keys and values)
function
                                                                        arrav unique(
array diff ukey()
                                                                       Removes duplicate values from an array
Compares arrays (keys only) through a user callback function
                                                                       array unshift()
array_fill()
                                                                       Adds one or more elements to the beginning of an array
Fills an array with values
                                                                        array_values(
array_fill_keys
                                                                       Returns all values of an array
                                                                        array_walk()
Fills an array with values, specifying keys
array_filter()
                                                                       Applies a user function to every element in an array
Filters the elements of an array via a callback function
                                                                        array_walk_recursive()
array flip(
                                                                       Recursively applies a user function to every element of an array
Exchanges all keys in an array with their associated values
                                                                        arsort(
                                                                       Sorts an associative array in descending order according to the
array intersect()
Compare arrays and return their matches (values only)
                                                                       value
array_intersect_assoc()
                                                                        assort()
Compare arrays and return their matches (keys and values)
                                                                       Sorts an associative array in ascending order according to the value
array intersect key()
                                                                        compact()
                                                                       Create an array containing variables and their values
Compare arrays and return their matches (keys only)
array intersect uassoc()
                                                                        count()
Compare arrays via a user-defined callback function (keys and
                                                                       Count all elements in an array, alternatively use sizeof
                                                                        current(
values)
array_intersect_ukey()
                                                                       Returns the current element in an array, an alternative is pos
Compare arrays via a user-defined callback function (keys only)
                                                                        each()
array_key_exists(
                                                                       Return the current key and value pair from an array
Checks if a specified key exists in an array, alternative:
key_exists
                                                                       Set the internal pointer to the last element of an array
array keys(
Returns all keys or a subset of keys in an array
                                                                       Import variables from an array into the current symbol table
array map(
Applies a callback to the elements of a given array
                                                                       Checks if a value exists in an arraykeyFetches a key from an array
                                                                        krsort()
array_merge()
                                                                       Sorts an associative array by key in reverse order
Merge one or several arrays
                                                                        ksort()
array_merge_recursive()
Merge one or more arrays recursively
                                                                       Sorts an associative array by key
array_multisort()
Sorts multiple or multi-dimensional arrays
                                                                       Assigns variables as if they were an array
array_pad()
Inserts a specified number of items (with a specified value)
                                                                       Sorts an array using a "natural order" algorithm independent of case
                                                                        natsort(
into an array
                                                                       Sorts an array using a "natural order" algorithm
array pop()
Deletes an element from the end of an array
                                                                        next()
array_product()
                                                                       Advance the internal pointer of an array
Calculate the product of all values in an array
array_push()
                                                                       Move the internal array pointer backwards
Push one or several elements to the end of the array
                                                                       Creates an array from a range of elements
array rand()
Pick one or more random entries out of an array
                                                                       Set the internal array pointer to its first element
array reduce()
Reduce the array to a single string using a user-defined
                                                                        rsort()
function
                                                                       Sort an array in reverse order
array_replace()
                                                                        shuffle()
Replaces elements in the first array with values from following
                                                                       Shuffle an array
                                                                        sort()
array_replace_recursive()
                                                                       Sorts an indexed array in ascending order
Recursively replaces elements from later arrays into the first
                                                                       Sorts an array with a user-defined comparison function
array
array_reverse()
Returns an array in reverse order
                                                                       Arrange an array by keys using a user-defined comparison function
```

```
PHP Cheat Sheet - DoubleDAmarasinghe @ github
                                                                        nrintf()
Categorize an array by values using a comparison function
                                                                        Outputs a formatted string
defined by the user
                                                                        quoted printable decode(
                                                                        Converts a quoted-printable string to 8-bit binary
String functions
addcslashes()
                                                                        quoted printable encode(
Returns a string with backslashes in front of specified
                                                                        Goes from 8-bit string to a quoted-printable string
characters
                                                                        Returns a string with a backslash before metacharacters
Returns a string with backslashes in front of characters that
need to be escaped
                                                                        Strips whitespace or other characters from the right side of a
hin2hex()
                                                                        string
Converts a string of ASCII characters to hexadecimal values
                                                                        setlocale()
                                                                        Sets locale information
chop()
Removes space or other characters from the right end of a string
                                                                        Calculates a string's SHA-1 hash
Returns a character from a specified ASCII value
                                                                        sha1_file()
 hunk_split(
                                                                        Does the same for a file
Splits a string into a series of smaller chunks
                                                                        similar text(
convert_cyr_string()
Converts a string from a Cyrillic character set to
                                                                        Determines the similarity between two strings
                                                                        soundex()
anotherconvert uudecode()
                                                                        Calculates the soundex key of a string
Decodes a uuencoded
                                                                        sprintf()
stringconvert_uuencode()
                                                                        Returns a formatted string
                                                                        sscanf()
Encodes a string using
uuencodecount_chars()
                                                                        Parses input from a string according to a specified format
Returns information about the characters in a string
                                                                        str getcsv
                                                                        Parses a CSV string into an array
Calculates a 32-bit CRC for a string
crypt()
                                                                        Replaces specified characters in a string with specified
                                                                        replacements (case-insensitive)
Returns a hashed string
echo() or echo
                                                                        str pad()
Outputs one or several strings
                                                                        Pads a string to a specified length
explode()
                                                                        str_repeat(
Breaks down a string into an array
                                                                        Repeats a string a preset number of times
                                                                        Replaces specified characters in a string (case-sensitive)
Writes a formatted string to a specified output stream
get_html_translation_table(
Returns the translation table used by htmlspecialchars() and
                                                                        Performs ROT13 encoding on a string
htmlentities()
                                                                        str shuffle(
                                                                        Randomly shuffles the characters in a string
hebrev()
Transforms Hebrew text to visual
                                                                        str split()
texthebrevc()
                                                                        Splits strings into arrays
Converts Hebrew text to visual text and implements HTML line
                                                                        str word count(
breaks
                                                                        Returns the number of words in a string
hex2bin()
Translate hexadecimal values to ASCII characters
                                                                        Case-insensitive comparison of two strings
                                                                        strcmp()
html entity decode()
Turns HTML entities to characters
                                                                        Binary safe string comparison (case sensitive)
htmlentities()
                                                                        strcoll()
Converts characters to HTML entities
                                                                        Compares two strings based on locale
htmlspecialchars decode(
                                                                        strcspn()
Transforms special HTML entities to characters
                                                                        Returns the number of characters found in a string before the
 htmlspecialchars(
                                                                        occurrence of specified characters
Switches predefined characters to HTML entities
                                                                        strip tags(
                                                                        Removes HTML and PHP tags from a string
Retrieves a string from the elements of an array, same as join()
                                                                        stripcslashes()
                                                                        Opposite of addcslashes()
Changes a string's first character to lowercase
                                                                        stripslashes(
levenshtein()
                                                                        Opposite of addslashes()
Calculates the Levenshtein distance between two strings
                                                                        stripos()
localeconv()
                                                                        Finds the position of the first occurrence of a substring within a
Returns information about numeric and monetary formatting for
                                                                        string (case insensitive)
the locale
 ltrim()
                                                                        Case-insensitive version of strstr()
Removes spaces or other characters from the left side of a
                                                                        strlen()
string
                                                                        Returns the length of a string
                                                                        strnatcasecmp(
                                                                        Case-insensitive comparison of two strings using a "natural order"
Calculates the MD5 hash of a string and returns it
                                                                        algorithm
md5 file()
Calculates the MD5 hash of a file
                                                                        strnatcmp()
                                                                        Same as the aforementioned but case sensitive
                                                                        strncasecmp()
Provides the metaphone key of a string
money_format()
                                                                        String comparison of a defined number of characters
Returns a string as a currency string
                                                                        (case insensitive)
 l_langinfo()
                                                                        strncmp(
Gives specific locale information
                                                                        Same as above but case-sensitive
                                                                        strpbrk()
Inserts HTML line breaks for each new line in a string
                                                                        Searches a string for any number of characters
number format()
                                                                        strpos()
Formats a number including grouped thousands
                                                                        Returns the position of the first occurrence of a substring in a
                                                                        string (case sensitive)
Returns the ASCII value of a string's first character
                                                                         strrchr(
parse_str()
                                                                        Finds the last occurrence of a string within another string
Parses a string into variables
```

Reverses a string

Outputs one or several strings

```
strripos()
                                                                       mysqli connect errno()
Finds the position of the last occurrence of a string's
                                                                       The error code from the last connection error
substring (case insensitive)
                                                                       mysali connect error(
                                                                       The error description from the last connection error
strrpos(
Same as strripos() but case sensitive
                                                                       mysqli_connect()
                                                                       Opens a new connection to the MySQL server
The number of characters in a string with only characters from
                                                                        mysqli_data_seek()
                                                                        Moves the result pointer to an arbitrary row in the result set
a specified list
 trstr()
                                                                        mysqli_debug()
                                                                       Performs debugging operations
Case-sensitive search for the first occurrence of a string
inside another string
                                                                        mysali dump debug info(
                                                                       Dumps debugging information into a log
strtok()
Splits a string into smaller chunks
                                                                        mysali errno()
                                                                       The last error code for the most recent function call
strtolower
Converts all characters in a string to lowercase
                                                                        mysqli_error_list(
strtoupper()
                                                                       A list of errors for the most recent function call
Same but for uppercase letters
                                                                        mvsali error()
                                                                        The last error description for the most recent function call
strtr()
Translates certain characters in a string, alternative:
                                                                       mysqli_fetch_all()
strchr()
substr()
                                                                       Fetches all result rows as an array
Returns a specified part of a string
                                                                        mvsali fetch array()
substr_compare()
                                                                       Fetches a result row as an associative, a numeric array, or both
Compares two strings from a specified start position up to a
                                                                        mysqli_fetch_assoc()
certain length, optionally case sensitive
                                                                       Fetches a result row as an associative array
                                                                        mysqli_fetch_field_direc
Counts the number of times a substring occurs within a string
                                                                       Metadata for a single field as an object
substr replace(
Replaces a substring with something else
                                                                       The next field in the result set as an object
                                                                       mvsali fetch fields(
Removes space or other characters from both sides of a string
                                                                       An array of objects that represent the fields in a result set
ucfirst()
                                                                        mvsali fetch lengths(
                                                                       The lengths of the columns of the current row in the result set
Transforms the first character of a string to uppercase
ucwords()
                                                                        mysqli_fetch_object()
Converts the first character of every word in a string to
                                                                       The current row of a result set as an object
uppercase
                                                                        mysqli fetch row()
                                                                        Fetches one row from a result set and returns it as an enumerated
Writes a formatted string to a specified output stream
                                                                       array
                                                                       mysqli field count()
vprintf()
                                                                       The number of columns for the most recent query
Outputs a formatted string
                                                                       mysqli field seek()
vsprintf()
Writes a formatted string to a variable
                                                                       Sets the field cursor to the given field offset
                                                                        mysqli_field_tell()
wordwrap()
Shortens a string to a given number of characters
                                                                       The position of the field cursor
Filter functions
                                                                        mysqli_free_result()
                                                                        Frees the memory associated with a result
Checks if a variable of the specified type exists
                                                                       mysqli get charset()
                                                                       A character set object
Returns the ID belonging to a named filter
                                                                       mysqli get client info()
                                                                       The MySQL client library version
filter input()
Retrieves a specified external variable by name and optionally
                                                                       mysqli_get_client_stats()
                                                                       Returns client per-process statistics
filters it
filter_input_array()
                                                                        mysqli_get_client_version(
Pulls external variables and optionally filters them
                                                                       The MySQL client library version as an integer
                                                                        mysqli_get_connection_stats()
filter list()
Returns a list of all supported filters
                                                                       Statistics about the client connection
filter_var_array()
                                                                       mysqli_get_host_info(
                                                                       The MySQL server hostname and the connection type
Gets multiple variables and optionally filters them
filter var()
                                                                       mysali get proto info(
Filters a variable with a specified filter
                                                                       The MySQL protocol version
HTTP functions
                                                                       mysqli_get_server_info()
                                                                       Returns the MySQL server version
Sends a raw HTTP header to the browser
                                                                        mysqli_get_server_version(
headers_list()
                                                                        The MySQL server version as an integer
A list of response headers ready to send (or already sent)
                                                                        mysqli_info()
                                                                       Returns information about the most recently executed
Checks if and where the HTTP headers have been sent
                                                                        query mysqli_init(
                                                                       Initializes MySQLi and returns a resource for use with
setcookie()
Defines a cookie to be sent along with the rest of the HTTP
                                                                       mysqli_real_connect()
headers
                                                                       mysqli_insert_id()
                                                                       Returns the auto-generated ID used in the last query
setrawcookie()
Defines a cookie (without URL encoding) to be sent along
                                                                       mysqli_kill()
MySQL functions
                                                                       Asks the server to kill a MySQL thread
mysqli affected rows()
                                                                        mysqli more results()
The number of affected rows in the previous MySQL operation
                                                                        Checks if there are more results from a multi query
mysqli autocommit(
                                                                       mysqli multi query()
Turn auto-committing database modifications on or off
                                                                       Performs one or more queries on the database
                                                                       mysqli next result(
mysqli change user(
Changes the user of the specified database connection
                                                                       Prepares the next result set from mysgli multi query()
mysqli_character_set_name(
                                                                        mysali num fields(
The default character set for the database connection
                                                                       The number of fields in a result set
mysqli_close()
                                                                        mysqli_num_rows()
Closes an open database connection
                                                                       The number of rows in a result set
mysqli commit()
Commits the current transaction
                                                                       Sets extra connect options and affect behavior for a connection
```

```
mysqli ping()
                                                                        date parse()
Pings a server connection or tries to reconnect if it has gone
                                                                        Returns an array with detailed information about a specified date
down
                                                                        date sub()
mvsali prepare()
                                                                        Subtracts days, months, years, hours, minutes and seconds from a
Prepares an SQL statement for execution
                                                                        date
mysqli_query()
                                                                        date_sun_info()
Performs a query against the database
                                                                        Returns an array containing information about sunset/sunrise and
mysqli_real_connect()
                                                                        twilight begin/end for a specified day and location
Opens a new connection to the MySQL server
mysqli_real_escape_string()
                                                                        The sunrise time for a specified day and location
Escapes special characters in a string for use in an SQL
                                                                        date sunset(
statement
                                                                        The sunset time for a specified day and location
mysqli real query()
                                                                        date_time_set()
Executes an SQL query
                                                                        Sets the time
mysqli_reap_async_query()
                                                                        date_timestamp_get()
Returns the result from async query
                                                                        Returns the Unix timestamp
mvsali refresh()
                                                                        date timestamp set
                                                                        Sets the date and time based on a Unix timestamp
Refreshes tables or caches or resets the replication server
information
                                                                        date timezone get()
mysqli_rollback()
                                                                        Returns the time zone of a given DateTime object
Rolls back the current transaction for the database
                                                                        date timezone set(
                                                                        Sets the time zone for a DateTime object
mysali select db()
                                                                        date()
Changes the default database for the connection
                                                                        Formats a local date and time
mysqli_set_charset(
                                                                        getdate()
Sets the default client character set
                                                                        Date/time information of a timestamp or the current local date/time
mysqli_set_local_infile_default()
Unsets a user-defined handler for the LOAD LOCAL INFILE command
                                                                        The current time
mysqli set local infile handler()
                                                                        gmdate()
Sets a callback function for the LOAD DATA LOCAL INFILE command
                                                                        Formats a GMT/UTC date and time
mvsali salstate(
                                                                        gmmktime(
Returns the SQLSTATE error code for the last MySQL operation
                                                                        The Unix timestamp for a GMT date
                                                                        gmstrftime(
mysqli_ssl_set()
                                                                        Formats a GMT/UTC date and time according to locale settings
Establishes secure connections using SSL
 ysqli_stat()
The current system status
                                                                        Formats a local time/date as an integer
                                                                        localtime()
mysqli_stmt_init()
                                                                        The local time
Initializes a statement and returns an object for use with
mysqli_stmt_prepare()
                                                                        microtime(
                                                                        The current Unix timestamp with microseconds
mysali store result(
Transfers a result set from the last query
                                                                        mktime()
mysqli_thread_id()
                                                                        The Unix timestamp for a date
The thread ID for the current connection
                                                                        strftime(
 ysqli_thread_safe
                                                                        Formats a local time and/or date according to locale settings
Returns if the client library is compiled as thread-safe
                                                                        Parses a time/date generated with strftime()
mvsali use result(
Initiates the retrieval of a result set from the last query
                                                                        strtotime()
executed using the mysqli_real_query()
                                                                        Transforms an English textual DateTime into a Unix timestamp
                                                                        time()
mysqli_warning_count()
The number of warnings from the last query in the connection
                                                                        The current time as a Unix timestamp
Date/Time functions
                                                                        timezone abbreviations list(
checkdate()
                                                                        Returns an array containing dst, offset, and the timezone name
Checks the validity of a Gregorian date
                                                                        timezone_identifiers_list
date add()
                                                                        An indexed array with all timezone identifiers
Adds a number of days, months, years, hours, minutes and
                                                                        timezone_location_get()
seconds to a date object
                                                                        Location information for a specified timezone
date_create_from_format()
                                                                        timezone_name_from_abbr()
Returns a formatted DateTime object
                                                                        Returns the timezone name from an abbreviation
date create()
                                                                        timezone name get(
                                                                        The name of the timezone
Creates a new DateTime object
date_date_set()
                                                                        timezone_offset_get()
Sets a new date
                                                                        The timezone offset from GMT
date_default_timezone_get()
                                                                        timezone_open(
Returns the default timezone used by all functions
                                                                        Creates a new DateTimeZone object
                                                                        timezone_transitions_get()
date_default_timezone_set()
Sets the default timezone
                                                                        Returns all transitions for the timezone
date_diff()
                                                                        timezone version get()
Calculates the difference between two dates
                                                                        Returns the version of the timezonedb
date format(
                                                                       Error functions
Returns a date formatted according to a specific format
                                                                        debug_backtrace()
date_get_last_errors(
                                                                        Used to generate a backtrace
Returns warnings or errors found in a date string
                                                                        debug_print_backtrace()
date_interval_create_from_date_string()
                                                                        Prints a backtrace
Sets up a DateInterval from relative parts of a
                                                                        error get last()
string date_interval_format()
                                                                        Gets the last error that occurred
Formats an interval
                                                                        error log()
date_isodate_set(
                                                                        Sends an error message to the web server's log, a file or a mail
Sets a date according to ISO 8601 standards
                                                                        account
date modify()
                                                                        error reporting()
                                                                        Specifies which PHP errors are reported
Modifies the timestamp
date_offset_get()
                                                                        restore_error_handler()
Returns the offset of the timezone
                                                                        Reverts to the previous error handler function
                                                                        restore_exception_handler()
date_parse_from_format()
Returns an array with detailed information about a specified
                                                                        Goes back to the previous exception handler
date, according to a specified format
                                                                        set error handler(
                                                                        Sets a user-defined function to handle script errors
```

```
set exception handler()
                                                                         [0-7]{1,3} - Character in octal notation
Sets an exception handler function defined by the
                                                                         x[0-9A-Fa-f]{1,2} - Character in hexadecimal notation
user trigger_error()
Generates a user-level error message, you can also use
                                                                        \u\{[0-9A-Fa-f]+\} - String as UTF-8 representation
                                                                       Date and Time formatting
user error()
                                                                        d - 01 to 31
Regular expression functions
                                                                        j - 1 to 31
                                                                        D - Mon through Sun
preg match()
                                                                        1 - Sunday through Saturday
Returns 1 if the pattern was found in the string and 0 if not
preg_match_all()
                                                                        N-1 (for Mon) through 7 (for Sat)
                                                                        w - 0 (for Sun) through 6 (for Sat)
Returns the number of times the pattern was found in the
                                                                        m - Months, 01 through 12
string, which may also be 0
                                                                        n - Months, 1 through 12
preg replace()
Returns a new string where matched patterns have been replaced
                                                                        F - January through December
with another string
                                                                        M- Jan through Dec
Numeric functions
                                                                        Y - Four digits year (e.g. 2018)
                                                                        y - Two digits year (e.g. 18)
Returns positive value of a number
                                                                         L - Defines whether it's a leap year (1 or 0)
sqrt()
                                                                        a - am and pm
Returns square root of a number
                                                                        A - AM and PM
                                                                        g - Hours 1 through 12
round()
                                                                        h - Hours 01 through 12
Rounds a floating number
                                                                        G - Hours 0 through 23
floor()
                                                                        H - Hours 00 through 23
Rounds a number down to a nearest integer
                                                                        i - Minutes 00 to 59
ceil()
Rounds a number up to a nearest integer
                                                                        s - Seconds 00 to 59
                                                                        Quantifiers
Generates a random integer
                                                                        \ensuremath{\text{n+}} - Matches any string that contains at least one \ensuremath{\text{n}}
                                                                        n* - Matches any string that contains zero or more occurrences of n
                                                                        n? - Matches any string that contains zero or one occurrences of n
Generates random number between defined inital and end number
                                                                        n{x} - Matches any string that contains a sequence of X n's
                                                                        n\{x,y\} - Matches any string that contains a sequence of X to Y n's
Returns x raised to the power of y
                                                                        n\{x,\} - Matches any string that contain a sequence of at least X n's
                                                                        Metacharacters
Returns the value of pi
                                                                        | - Find a match for any one of the patterns separated by | as in:
min()
Returns the lowest value from an array
                                                                        cat|dog|fish
                                                                         . - Find just one instance of any character
                                                                         ^ - Finds a match as the beginning of a string as in: ^Hello
Returns the highest value from an array
fmod()
                                                                        $ - Finds a match at the end of the string as in: World$
Returns the remainder from x/y {%}
                                                                        \d - Find a digit
                                                                         \s - Find a whitespace character
bindec()
                                                                         \b - Find a match at the beginning of a word like this: \bWORD, or
Converts a binary number to a decimal number
decbin()
                                                                             at the end of a word like this: WORD\b
                                                                        \uxxxx - Find the Unicode character specified by the hexadecimal
Converts a decimal number to a binary number
                                                                                 number xxxx
Converts a degree value to a radian value
                                                                        Regular expression modifiers
                                                                           Performs a case-insensitive search
rad2deg()
Converts a radian value to a degree value
                                                                        m - Performs a multiline search (patterns that search for the
Directory functions
                                                                            beginning or end of a string will match the beginning or end of
                                                                             each line)
getcwd()
Get current working directory
                                                                        u - Enables correct matching of UTF-8 encoded patterns
mkdir()
                                                                       Regular expression patterns
Make directory
                                                                        [abc] - Find one character from the options between the brackets
                                                                         [^abc] - Find any character NOT between the brackets
Remove directory
                                                                         [0-9] - Find one character from the range 0 to 9
dirname()
                                                                        Grouping
Directory name
                                                                        <?php
                                                                        $str = "Apples and bananas.";
Line number
                                                                        pattern = "/ba(na){2}/i";
file exists()
Checks if file exists and returns Boolean value
                                                                        echo preg_match($pattern, $str); // Outputs 1
unlink()
Remove file
 s file()
Boolean
is dir()
Boolean
scan_dir()
Returns array of files present in the directory
Feturns file size in bytes
filectime(
File created time (timestamps)
pathinfo(
Returns array / string based on arguments
copy()
Copy file
Escape characters
\n - Line feed
\r - Carriage return
\t - Horizontal tab
\v - Vertical tab
\e - Escape
\f - Form feed
\\ − Backslash
```

\\$ - Dollar sign √, – Single quote \" - Double quote
